

1. ****Regular Expressions:****

- ``digit [0-9]*``: This defines a regular expression for matching zero or more digits.
- ``letter [a-zA-Z]``: This defines a regular expression for matching a single letter.
- ``id {letter}({letter}|{digit})*``: This defines a regular expression for matching identifiers. An identifier starts with a letter and can be followed by zero or more letters or digits.
- ``int_num {digit}+``, ``uint_num 0({int_num})``: These regular expressions define signed and unsigned integers. An unsigned integer can be either 0 or a sequence of one or more digits.

2. ****Floating-Point Numbers:****

- ``float_num ({int_num}\.{digit}+)|({int_num}\.)(\.{digit}+)``: This regular expression matches different forms of floating-point numbers. It can be an integer part followed by a decimal point and one or more digits (``{int_num}\.{digit}+``), an integer part followed by just a decimal point (``{int_num}\.``), or just a decimal point followed by one or more digits (``\.{digit}+``).

3. ****Exponential Notation:****

- ``exp_num ({int_num}|{float_num})[eE][+-]?{int_num}``: This regular expression matches numbers in exponential notation. It can be an integer or float part followed by ``e`` or ``E``, an optional ``+`` or ``-``, and then one or more digits.

4. ****Tokens and Actions:****

- The section after the ``%%`` delimiter contains rules for recognizing various tokens.
- For example, ``"/`` is a pattern to match a double forward slash, and the action ``{scom=1;}`` sets the single-line comment flag to 1.
- Keywords, relational operators, assignment operator, etc. are recognized based on the provided patterns.

5. ****Ignoring Comments:****

- ``/* ... */`` style comments are ignored using the rules for ``"/*`` and ``*/``.
- Single-line comments are ignored using the rule for ``"/``.

6. **Printing and Storing:**

- When a token is recognized, it prints a message to the output file (`yyout`) indicating the type of the token.
- Identifiers are also stored in the symbol table (`st`) if they haven't been encountered before.

7. **Main Function:**

- `main()` opens the input and output files, calls `yylex()` to start the lexical analysis, and then prints the contents of the symbol table.

8. **`look_up` Function:**

- This function checks if a given identifier (`id`) is already in the symbol table.

9. **`yywrap` Function:**

- This function is used to indicate the end of input.

10. **File Handling:**

- The program reads from a file named `x.txt` and writes to a file named `y.txt`.

This Lex program will tokenize the input based on the specified rules and print the results to `y.txt`. The program also maintains a symbol table and handles different types of numeric constants and identifiers as per the provided regular expressions.

Commands to run the program :

```
C:\Windows\System32\cmd.exe
Microsoft Windows [Version 10.0.22621.2283]
(c) Microsoft Corporation. All rights reserved.

C:\Users\venka\OneDrive\Desktop\CD Lab>flex lex.l
C:\Users\venka\OneDrive\Desktop\CD Lab>gcc lex.yy.c
C:\Users\venka\OneDrive\Desktop\CD Lab>a.exe
C:\Users\venka\OneDrive\Desktop\CD Lab>
```

35°C
